# 1 Problem Statement

The problem deals with constructing a fog diagram of the electron/charge density of molecules and atoms in primitive cells. The charge density distribution is obtained through VASP using the ‘jasp’ code.

## 2 Implementation Code

### 2.1 Geometry Optimization

The molecules or primitive cells are relaxed using the following general code set:

---

```
1 from ase import Atom, Atoms
2 from ase.data.molecules import molecule
3 from jasp import *
4
5 # Create the initial structure
6 mol1 = molecule('CH3CONH2')
7 mol1.set_cell([10, 10, 10], scale_atoms=False)
8 mol1.center()
9
10 ready = True
11
12 emol=0
13
14 # Make a geometry optimized structure of a molecule and get the charge density
15 # Default calculations made with molecule at center of unit cell for better visualization
16 with jasp('molecules/wgs/CH3CONH2-center',
17           xc='PBE',
18           encut=350, #Energy cutoff
19           ismear=0, #Smearing of orbitals
20           ibrion=2, #Geometry optimization
21           nsf=8,
22           nbands=2*6 + 1*3 + 1*3 + 5*1 + 3,
23           ispin=2, #Spin polarization
24           atoms=mol1) as calc:
25     try:
26         emol = mol1.get_potential_energy()
27         fmol = mol1.get_forces()
28         print calc
29     except (VaspSubmitted, VaspQueued):
30         ready = False
31
32 print emol
33 print fmol
```

---

In this code snippet, ibrion=2 is used for geometry optimization. One could also use an equation of state method. The main outcome of this step

is that an optimized structure must be obtained for which the charge density distribution file ‘CHGCAR’ has been created.

## 2.2 Plotting Atoms

The plotting procedure is executed next. First, atoms are plotted as solid spheres:

---

```
1 from jasp import *
2 from enthought.mayavi import mlab
3 from ase.data import vdw_radii
4 from ase.data.colors import cpk_colors
5 import numpy as np
6
7
8 mol_name = 'CH3CONH2'
9
10 #Read molecule data from exisiting folder
11 with jasp('molecules/wgs/{0}-center'.format(mol_name)) as calc:
12     atoms = calc.get_atoms()
13     atoms.center()
14     x, y, z, cd = calc.get_charge_density()
15
16 mlab.figure(bgcolor=(1, 1, 1), size=(350,350)) # make a white figure
17
18 atoms_x = []
19 atoms_y = []
20 atoms_z = []
21
22 # Plot the atoms as spheres
23 for atom in atoms:
24     mlab.points3d(atom.x,
25                   atom.y,
26                   atom.z,
27                   scale_factor=vdw_radii[atom.number]/2., #this determines the size of the atom
28                   resolution=20,
29                   # a tuple is required for the color
30                   color=tuple(cpk_colors[atom.number]),
31                   scale_mode='none')
32     atoms_x.append(atom.x)
33     atoms_y.append(atom.y)
34     atoms_z.append(atom.z)
35     #print vdw_radii[atom.number]/2.
```

---

## 2.3 Plotting Bonds

Plotting the bonds in the case of molecules is slightly complicated. To figure out the number and participants in the bonds, the nearest neighbours of each atom must be known. This can either be calculated explicitly or can be read from the ‘OUTCAR’ file. Since reading the file is probably computationally

more efficient, I have used that method to create the nearest neighbour list. From this list, covalent bonds for each atom are drawn to its nearest neighbours. The code for this functionality is as follows:

---

```

1  #Plot bonds as tubes
2  #Get positions of atom
3  bonds_pos = []
4  f = open('molecules/wgs/{0}-center/OUTCAR'.format(mol_name),'r')
5  while ('ion position' not in f.readline()):
6      pass
7  r1 = np.arange(len(atoms_x))
8  for i in r1:
9      a = f.readline()
10     data1 = np.fromstring(a,sep=' ')
11     bonds_pos = np.append(bonds_pos,data1[1:])
12     i+=1
13  f.close()
14  bonds_pos *=10
15
16  #Get nearest neighbour list to draw bonds
17  f = open('molecules/wgs/{0}-center/OUTCAR'.format(mol_name),'r')
18  while ('ion position' not in f.readline()):
19      pass
20  r1 = np.arange(len(atoms_x))
21  for i in r1:
22      a = f.readline()
23      index = 0
24      for a1 in a:
25          if '-' not in a1:
26              index +=1
27          else:
28              break
29      a2 = a[index+1:]
30      data2 = np.fromstring(a2, sep=' ')
31      r2 = np.arange(0,len(data2),2)
32      for j in r2:
33          ind = int(data2[j])-1
34          mlab.plot3d([bonds_pos[ind*3 + 0],bonds_pos[i*3 + 0]], [bonds_pos[ind*3 + 1],bonds_pos[i*3 + 1]],
35                     [bonds_pos[ind*3 + 2],bonds_pos[i*3 + 2]],tube_radius=0.07, colormap='Reds')
36      i+=1
37  f.close()

```

---

This code does not distinguish between single/double/triple bonds and will only draw a single tube for each case. However, when looking at the electron density, the difference between these various kinds of bonds can be observed (I have plotted cases of C<sub>2</sub>H<sub>6</sub>, C<sub>2</sub>H<sub>4</sub> and C<sub>2</sub>H<sub>2</sub>). Also, it can be noticed that the positions of the atoms are read again (they were previously obtained using `get_atoms()` for plotting the atoms). This is because the atom list in 'OUTCAR' is not similar to the atom list output using `get_atoms()`.

## 2.4 Plotting Cloud/Fog

Lastly, the charge density cloud is plotted using volume rendering via the following code:

---

```
1  #Draw electron density as fog
2  source = mlab.pipeline.scalar_field(x,y,z,cd)
3  min = cd.min()
4  max = cd.max()
5  vol = mlab.pipeline.volume(source, vmin=min+0.008*(max-min), vmax=min + 0.1*(max-min))
6
7  #Save image at different angles
8  mlab.view(azimuth=0, elevation=90, distance=10)
9  mlab.savefig('images/{0}_1.png'.format(mol_name.lower()))
10 mlab.view(azimuth=90, elevation=0, distance=10)
11 mlab.savefig('images/{0}_3.png'.format(mol_name.lower()))
12 mlab.show()
```

---

The 'vmax' and 'vmin' parameters are set to adjust how the cloud is visualized. They had to be adjusted a significant amount and the present combination seemed to provide the best results in terms of how well the charge density features could be viewed.

## 3 Instructions and Files

The geometry optimization code is present in the file 'mol.org'. The 'mol\_name' variable needs to be changed accordingly by the user. Also, the parameters for optimization should be adjusted as required. Upon execution, the code will create a folder 'mol\_name-center' in the 'molecules' folder.

To create the images, there are two files present - 'viz\_mol.org' and 'vis\_latt.org' for molecules and crystal structures respectively. They will only work if the optimized folders created by 'mol.org' or from any other source is present in the 'molecules' folder. In each of these files, the user must specify the molecule/crystal whose charge density he wants to visualize using the 'mol\_name' variable. Upon execution, image files 'mol\_name\_1.png' and 'mol\_name\_2.png' will be created in the 'images' folder. These images have different azimuth and elevation parameters. The user can adjust these as required if he wants to.

## 4 Results

The following are images of the molecules studied, the asymmetrical ones having two viewing directions.

### 4.1 CO<sub>2</sub>

### 4.2 CO

### 4.3 N<sub>2</sub>

### 4.4 H<sub>2</sub>O

#### 4.5 CH<sub>4</sub>

#### 4.6 C<sub>2</sub>H<sub>6</sub>

#### 4.7 $\text{C}_2\text{H}_4$

#### 4.8 $\text{C}_2\text{H}_2$

#### 4.9 $\text{CH}_3\text{CH}_2\text{OH}$

#### 4.10 $\text{CH}_3\text{CONH}_2$

#### 4.11 C<sub>6</sub>H<sub>6</sub>

#### 4.12 Ta

#### 4.13 TaC

#### 4.14 Graphite
